a

Testing the time x treatment interaction with few clusters

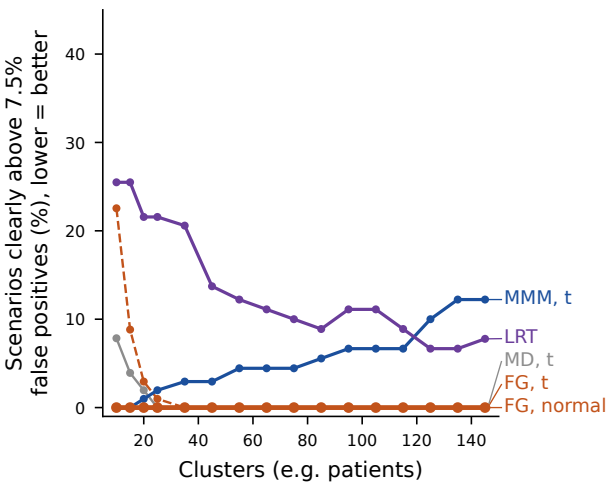

GEE with the Fay-Graubard correction and a t reference (N - p degrees of freedom), at any number of clusters (e.g. patients) and of occasions

With 2-3 occasions and up to 25 clusters (e.g. patients) it gives no result in 4-7 datasets out of 10 and is often conservative: there no method is both available and calibrated. The likelihood-ratio test answers more often but is clearly above 7.5% false positives in over a third of those scenarios.
