a

Testing the time x treatment interaction with few clusters

Marginalized multilevel model with a t reference (N - p df) and a convergence check: refit without the latent-SD slope if the fit fails or the slope is at 0; any number of clusters and occasions

Alternative: GEE, Fay-Graubard, t (about 10% false positives with <= 25 clusters and growing variability)

2-3 occasions, <= 25 clusters: both answer in about 4 datasets of 10; no method is both available and calibrated
